

Topic :-DIFFERENTIAL EQUATIONS

1 (a)

Given equation can be rewritten as

$$\frac{dx}{dy} + \frac{1}{(1+y^2)}x = \frac{e^{\tan^{-1}y}}{(1+y^2)}$$

$$\therefore IF = e^{\int \frac{1}{1+y^2} dy} = e^{\tan^{-1}y}$$

\therefore Required solution is

$$xe^{\tan^{-1}y} = \int \frac{e^{\tan^{-1}y} e^{\tan^{-1}y}}{1+y^2} dy$$

Put $e^{\tan^{-1}y} = t \Rightarrow e^{\tan^{-1}y} \frac{1}{1+y^2} dy = dt$

$$\therefore xe^{\tan^{-1}y} = \int t dt = \frac{t^2}{2} + c$$

$$\Rightarrow 2xe^{\tan^{-1}y} = e^{2 \tan^{-1}y} + k$$

2 (b)

Given, $\frac{dy}{dx} = \log(x+1)$

$$\Rightarrow dy = \log(x+1) dx$$

$$\Rightarrow \int dy = \int \log(x+1) dx$$

$$\Rightarrow y = (x+1)\log|x+1| - x + c$$

$$\therefore x = 0, y = 3$$

$$\therefore c = 3$$

$$\therefore y = (x+1)\log|x+1| - x + 3$$

3 (d)

Given equation is

$$\frac{d^2y}{dx^2} = \frac{\log x}{x^2}$$

On integrating, both sides we get

$$\int \frac{d^2y}{dx^2} dx = \int \frac{\log x}{x^2} dx$$

$$\Rightarrow \frac{dy}{dx} = -\frac{\log x}{x} + \int \frac{1}{x^2} dx + c$$

$$\Rightarrow \frac{dy}{dx} = -\frac{\log x}{x} - \frac{1}{x} + c$$

At $x = 1, y = 0$ and $\frac{dy}{dx} = -1 \Rightarrow c = 0$

$$\therefore \frac{dy}{dx} = -\frac{(\log x + 1)}{x}$$

Again on integrating, both sides we get

$$\int \frac{dy}{dx} dx = - \int \frac{\log x + 1}{x} dx + c_1$$

$$y = -\frac{1}{2}(\log x)^2 - \log x + c_1$$

At $x = 1, y = 0$

$$\Rightarrow c_1 = 0$$

$$\therefore y = -\frac{1}{2}(\log x)^2 - \log x$$

5 **(b)**

Given equation is

$$\sin^{-1} x + \sin^{-1} y = c \dots(i)$$

On differentiating Eq. (i) w.r.t.x, we get

$$\frac{1}{\sqrt{1-x^2}} + \frac{1}{\sqrt{1-y^2}} \frac{dy}{dx} = 0$$

$$\Rightarrow \frac{dy}{dx} = -\frac{\sqrt{1-y^2}}{\sqrt{1-x^2}}$$

$$\Rightarrow \sqrt{1-x^2} dy + \sqrt{1-y^2} dx = 0$$

This is the required differential equation.

6 **(d)**

Given that, $\frac{dy}{dx} = 1 + y^2$

$$\Rightarrow \frac{dy}{1+y^2} = dx$$

On integrating both sides, we get

$$\int \frac{dy}{1+y^2} = \int dx$$

$$\Rightarrow \tan^{-1} y = x + c$$

At $x = 0, y = 0$, then $c = 0$

At $x = \pi, y = 0$, then $\tan^{-1} 0 = \pi + c \Rightarrow c = -\pi$

$$\therefore \tan^{-1} y = x \Rightarrow y = \tan x = \phi(x)$$

Therefore, solution becomes $y = \tan x$

But $\tan x$ is not continuous function in $(0, \pi)$

So, $\phi(x)$ is not possible in $(0, \pi)$.

7 **(c)**

Let $p = \frac{dy}{dx}$

\therefore Given differential equation reduces to

$$p^2 - xp + y = 0$$

Differentiating both sides w.r.t. x , we get

$$2p \frac{dp}{dx} - x \frac{dp}{dx} - p + p = 0$$

$$\Rightarrow \frac{dp}{dx}(2p - x) = 0$$

$$\Rightarrow \text{Either } \frac{d^2y}{dx^2} = 0 \text{ or } \frac{dy}{dx} = \frac{x}{2}$$

$$\Rightarrow y = 2x - 4 \text{ will satisfy.}$$

8 (c)

$$\text{Given, } y = a \sin(5x + c)$$

$$\Rightarrow \frac{dy}{dx} = 5a \cos(5x + c)$$

$$\Rightarrow \frac{d^2y}{dx^2} = -25a \sin(5x + c) = -25y$$

9 (c)

$$\text{Given, } (1 - x^2) \frac{dy}{dx} - xy = 1$$

$$\Rightarrow \frac{dy}{dx} - \frac{x}{1 - x^2} y = \frac{1}{1 - x^2}$$

This is a linear equation, comparing with the equation

$$\frac{dy}{dx} + Py = Q$$

$$\Rightarrow P = -\frac{x}{1 - x^2}, Q = \frac{1}{1 - x^2}$$

$$\therefore IF = e^{\int P dx} = e^{\int \frac{-x}{1-x^2} dx}$$

$$\Rightarrow IF = e^{\frac{1}{2} \log(1-x^2)} = \sqrt{1-x^2}$$

10 (c)

We have,

$$\text{Slope} = \frac{dy}{dx} \Rightarrow \frac{dy}{dx} = \frac{1}{2y} \Rightarrow 2y dy = dx$$

$$\text{Integrating both sides, we get } y^2 = x + C$$

This passes through (4, 3)

$$\therefore 9 = 4 + C \Rightarrow C = 5$$

$$\text{So, the equation of the curve is } y^2 = x + 5$$

11 (a)

The given differential equation is

$$\frac{dy}{dx} + y \frac{\sin x}{\cos x} = \frac{1}{\cos x}$$

$$\therefore IF = e^{\int \frac{\sin x}{\cos x} dx} = e^{\log \sec x} = \sec x$$

12 (b)

$$\text{Given, } \frac{dy}{dx} + \frac{2x}{1+x^2} y = \frac{1}{(1+x^2)^2}$$

$$\therefore IF = e^{\int \frac{2x}{1+x^2} dx} = e^{\log(1+x^2)} = 1 + x^2$$

The complete solution is

$$y(1+x^2) = \int (1+x^2) \cdot \frac{1}{(1+x^2)^2} dx + c$$

$$\Rightarrow y(1+x^2) = \tan^{-1} x + c$$

13 (b)

∴ The order of the differential equation is the order of highest derivative in the differential equation.

∴ The second order differential equation is in option (b) i.e.,

$$y'y'' + y = \sin x$$

14 (c)

$$\text{Given, } \frac{dy}{dx} = \frac{\sqrt{1-y^2}}{y}$$

$$\Rightarrow \int \frac{y}{\sqrt{1-y^2}} dy = \int dx$$

$$\Rightarrow -\sqrt{1-y^2} = x + c$$

$$\Rightarrow (x+c)^2 + y^2 = 1$$

∴ Centre $(-c, 0)$, radius = 1

15 (c)

$$\text{Given, } \frac{dy}{dx} + y = 2e^{2x}$$

$$\therefore \text{IF} = e^{\int 1 dx} = e^x$$

∴ Required solution is

$$ye^x = 2 \int e^{2x} e^x dx = \frac{2}{3} e^{3x} + c$$

$$\Rightarrow y = \frac{2}{3} e^{2x} + ce^{-x}$$

16 (c)

$$\text{Given, } y = \sin^{-1} x$$

$$\Rightarrow \frac{dy}{dx} = \frac{1}{\sqrt{1-x^2}} \quad \dots(i)$$

$$\Rightarrow \frac{d^2y}{dx^2} = \frac{0 - \frac{1}{2} \cdot \frac{(-2x)}{\sqrt{1-x^2}}}{(\sqrt{1-x^2})^2}$$

$$\Rightarrow (1-x^2) \frac{d^2y}{dx^2} = x \frac{dy}{dx} \dots[\text{from Eq.(i)}]$$

17 (a)

$$\text{Given, } \frac{dy}{dx} = 2\cos x - y\cos x \operatorname{cosec} x$$

$$\Rightarrow \frac{dy}{dx} + y\cot x = 2\cos x$$

$$\therefore \text{IF} = e^{\int \cot x dx} = e^{\log(\sin x)} = \sin x$$

$$\therefore \text{Solution is } y\sin x = \int 2\cos x \sin x dx + c$$

$$\Rightarrow y\sin x = \int \sin 2x dx + c$$

PE

$$\Rightarrow y \sin x = \frac{-\cos 2x}{2} + c$$

$$\text{At } x = \frac{\pi}{4}, y = \sqrt{2}$$

$$\therefore \sqrt{2} \sin \frac{\pi}{4} = \frac{-\cos 2(\pi/4)}{2} + c$$

$$\Rightarrow c = 1$$

$$\therefore y \sin x = -\frac{1}{2} \cos 2x + 1$$

$$\Rightarrow y = -\frac{1}{2} \cdot \frac{\cos 2x}{\sin x} + \operatorname{cosec} x$$

$$\Rightarrow y = -\frac{1}{2 \sin x} (1 - 2 \sin^2 x) + \operatorname{cosec} x$$

$$\Rightarrow y = \frac{1}{2} \operatorname{cosec} x + \sin x$$

18 **(b)**

$$\text{Given, } \frac{\tan^{-1} x}{1+x^2} dx + \frac{y}{1+y^2} dy = 0$$

$$\Rightarrow \frac{(\tan^{-1} y)^2}{2} + \frac{1}{2} \log(1+y^2) = \frac{c}{2} \quad [\text{integrating}]$$

$$\Rightarrow (\tan^{-1} x)^2 + \log(1+y^2) = c$$

19 **(d)**

$$\text{Given, } \frac{dy}{dx} - y \tan x = -2 \sin x$$

$$\therefore \text{IF} = e^{-\int \tan x \, dx} = \cos x$$

\therefore Solution is

$$y(\cos x) = \int -2 \sin x \cos x \, dx + c = -\int \sin 2x \, dx + c$$

$$\Rightarrow y \cos x = \frac{\cos 2x}{2} + c$$

20 **(a)**

$$\text{Given, } \frac{dy}{dt} - \left(\frac{1}{1+t}\right)y = \frac{1}{(1+t)} \text{ and } y(0) = -1$$

$$\begin{aligned} \therefore \text{IF} &= e^{\int -\left(\frac{1}{1+t}\right) dt} = e^{-\int \left(1 - \frac{1}{1+t}\right) dt} \\ &= e^{-t + \log(1+t)} = e^{-t}(1+t) \end{aligned}$$

\therefore Required solution is

$$\begin{aligned} ye^{-t}(1+t) &= \int \frac{1}{1+t} e^{-t}(1+t) dt + c \\ &= \int e^{-t} dt + c \end{aligned}$$

$$\Rightarrow ye^{-t}(1+t) = -e^{-t} + c$$

$$\text{Since, } y(0) = -1$$

$$\Rightarrow c = 0$$

$$\therefore y = -\frac{1}{(1+t)}$$

$$\Rightarrow y(1) = -\frac{1}{2}$$
